stack

popcorn

# Last Time: The Stack

程序代写代做 CS编程辅导

The **stack** is a data structure that is managed at the end of the RAM managed using **SP = R1** and **pop**

Runtime calls and interrupts use the stack to save critical registers (PC and SR) before execution and restore these with `ret/reti`

**Word  
Address**

**RAM**

0x1C00

0x1C02

0x1C04

0x1C06

⋮  
⋮  
⋮

0x23FE

**Stack**

We can use the stack to save/restore additional registers (R4 – R15) during subroutine calls and interrupts

Assignment Project Exam Help

We can create variables during runtime without initializing/reserving them at compile time

⇒ **dynamic data allocation**

And we can use the stack to pass input/output to/from a subroutine

← **Stack starts here**

# Passing Data to Subroutines

程序代写代做 CS编程辅导

A **subroutine** is a sequence of instructions that performs one specific task

Most subroutines take some arguments and return some output

Input/output should **not** be shared – otherwise subroutine cannot be reused for different sets of input

e.g., subroutine to multiply two unsigned bytes

output  
 $x*y$

When called

```

;-----
; Subroutine: x_Times_y
; Inputs: unsigned byte x in R5 -- returned unchanged
;         unsigned byte y in R6 -- returned unchanged
;
; Output: unsigned number in R12 -- R12 = R5 * R6
;-----

```

subroutine

When the

caller

In these examples the **input/output is passed over core registers**

- How data is passed is specified in the contract

# Passing Data over the Stack

程序代写代做 CS编程辅导

Another way to pass data between caller and subroutine is to use the **stack**

**When calling the subroutine we need to pass  $x$  and  $y$  to the subroutine**

- We place  $x$  and  $y$  on the stack where the subroutine can find it

**When the subroutine returns it needs to pass the output to the caller**

- Subroutine places  $x * y$  on the stack where we can find it

In both cases, not an absolute address, but relative to the stack pointer  $SP$

**We define a **stack frame** with fields for **input**, **output** and **return address****

- caller places **input(s)** into the stack frame using push
- with the call the return address (PC) is placed into the stack frame
- subroutine places its **output(s)** into the stack frame
- returning from the subroutine (ret) removes the saved PC from stack
- caller cleans up the rest of the stack

# Example Stack Frame

程序代写代做 CS编程辅导

The subroutine contract specifies the structure of the **stack frame**

subroutine will see when it is first called  
e.g., a stack frame with two input values and one output value

Caller pushes input\_1, then input\_2

• With the subroutine call PC is placed onto the stack  
WeChat: cstutorcs

Assignment Project Exam Help

• reads input\_1 and input\_2

Email: tutormcs@163.com

• computes and writes output into the stack

frame  
QQ: 749389476

ret from subroutine removes PC from stack

Caller  
http://tutormcs.com

• reads output from stack frame

• cleans up the rest of the stack

SP

# Example Stack Frame

程序代写代做 CS编程辅导

Subroutine

- reads `input_1` and `input_2`
- computes and writes `output` to the stack frame

How does the subroutine access these elements of the stack frame?

Indexed Mode  
of addressing

Assignment Project Exam Help

even this works!
